

Kerogen thermal destruction

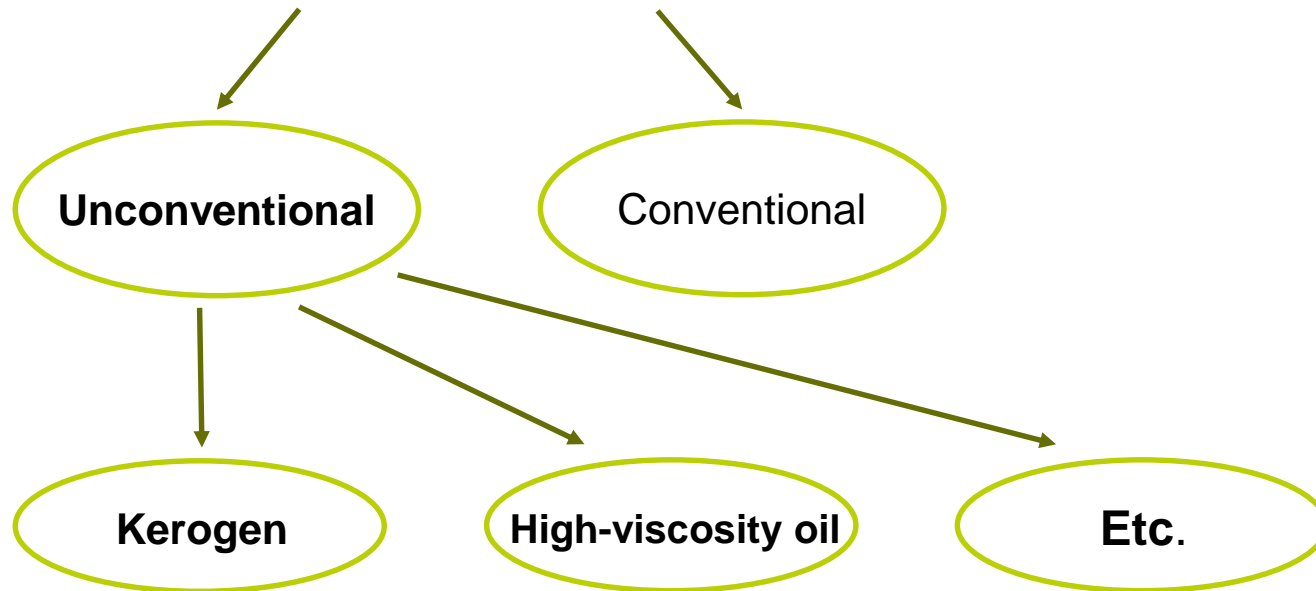

Nick Mitiurev

Supervisor: Spasennykh Mikhail

Content

1. What is Kerogen?
2. Methods for kerogen analysis
 - 2.1. Solid State NMR
 - 2.2. Kinetic experiments on pyrolytic instrument
 - 2.3. GC-GC-MS (Two-dimensional gas chromatography coupled with mass spectrometry)
3. Conclusions

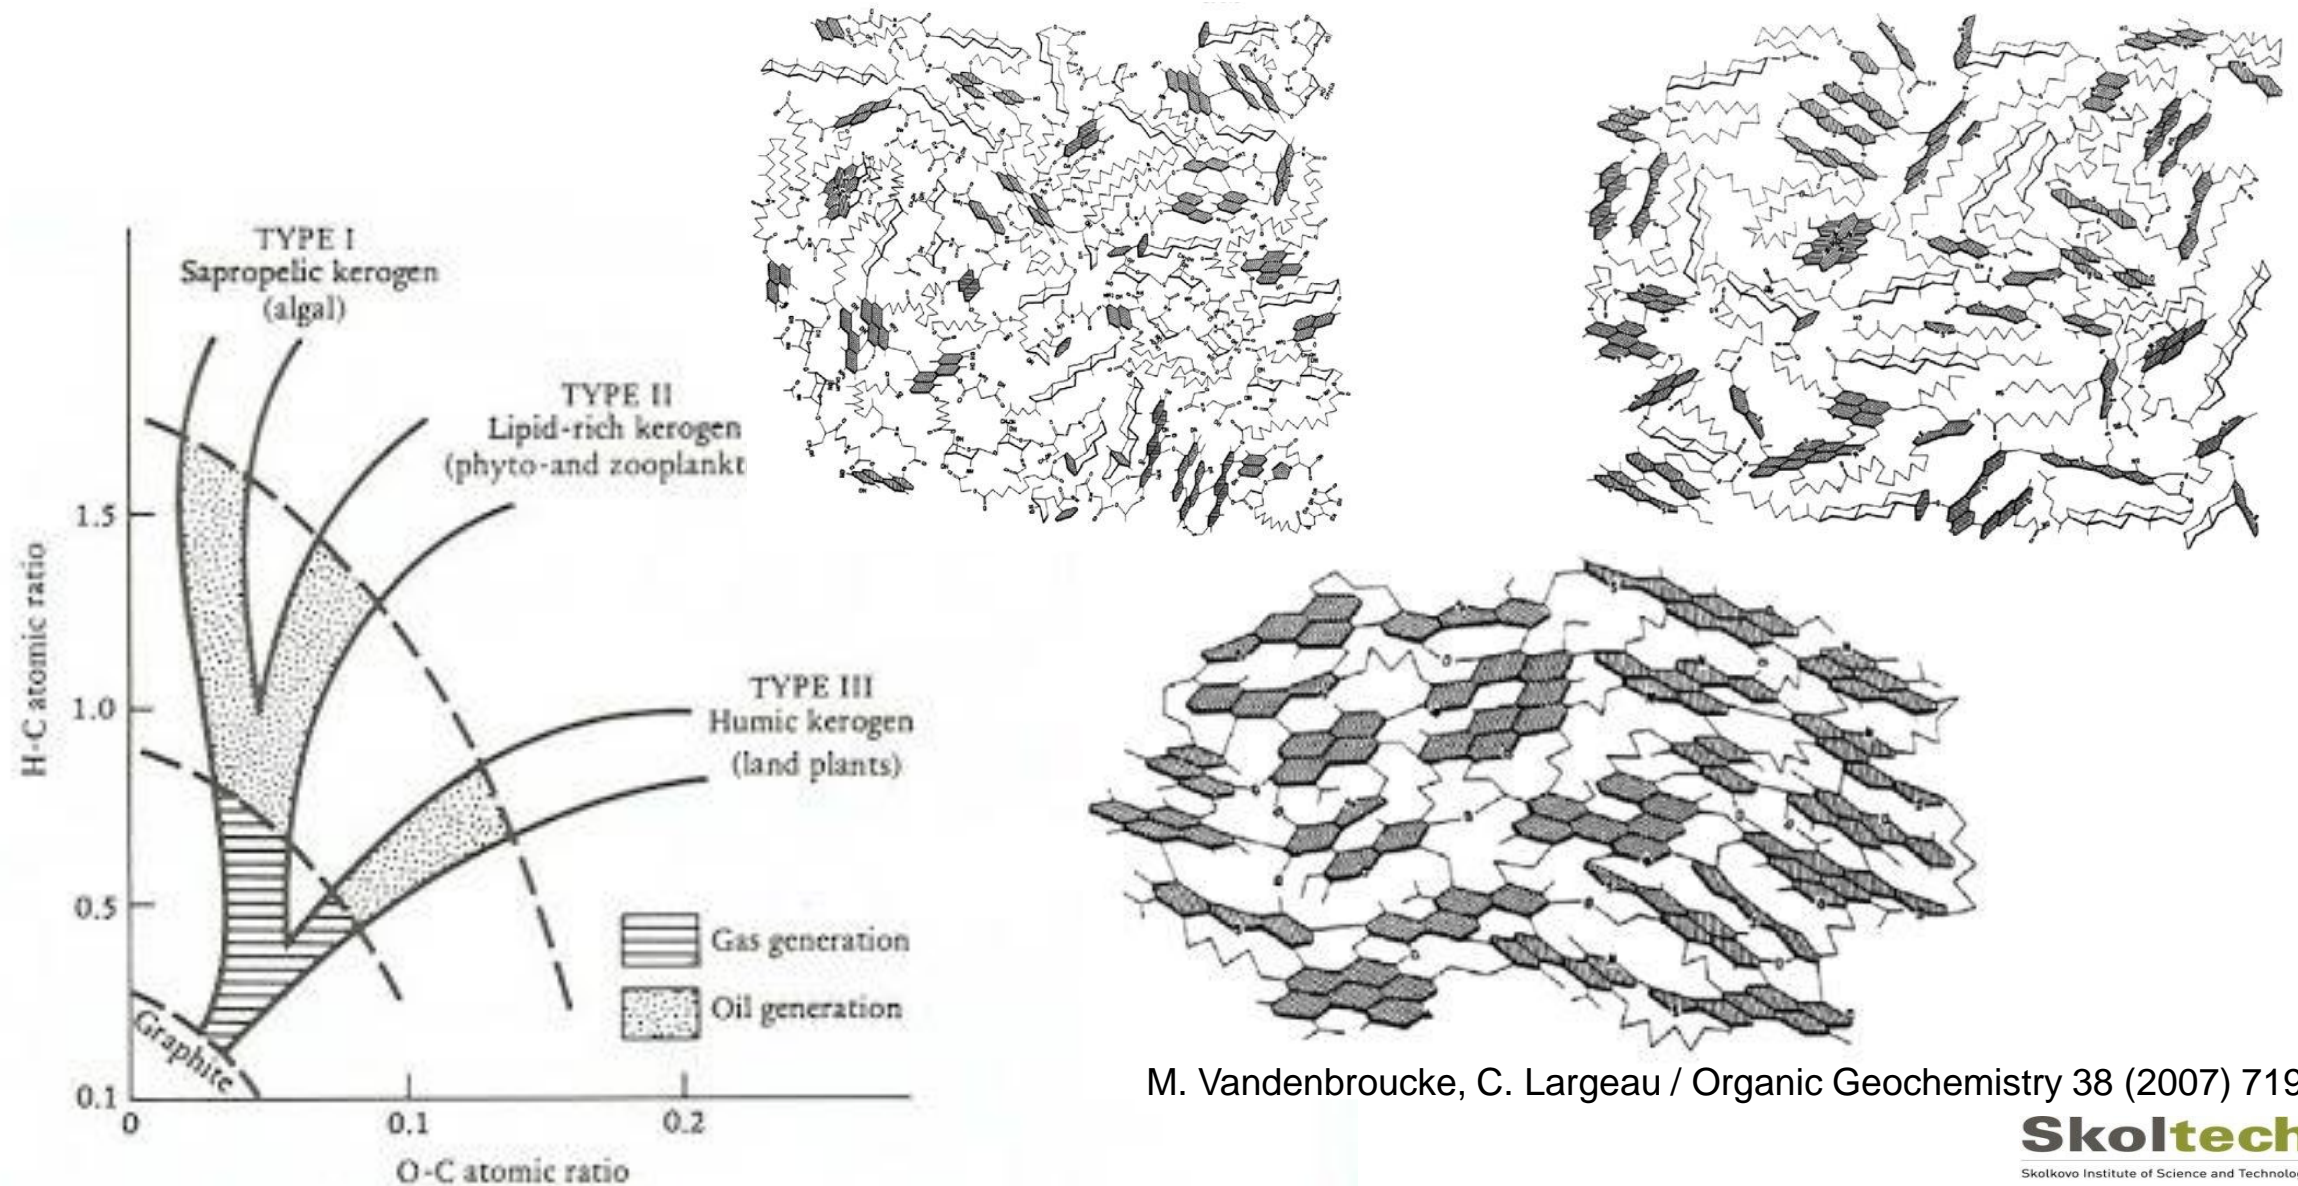

Hydrocarbon Resources

Tasks

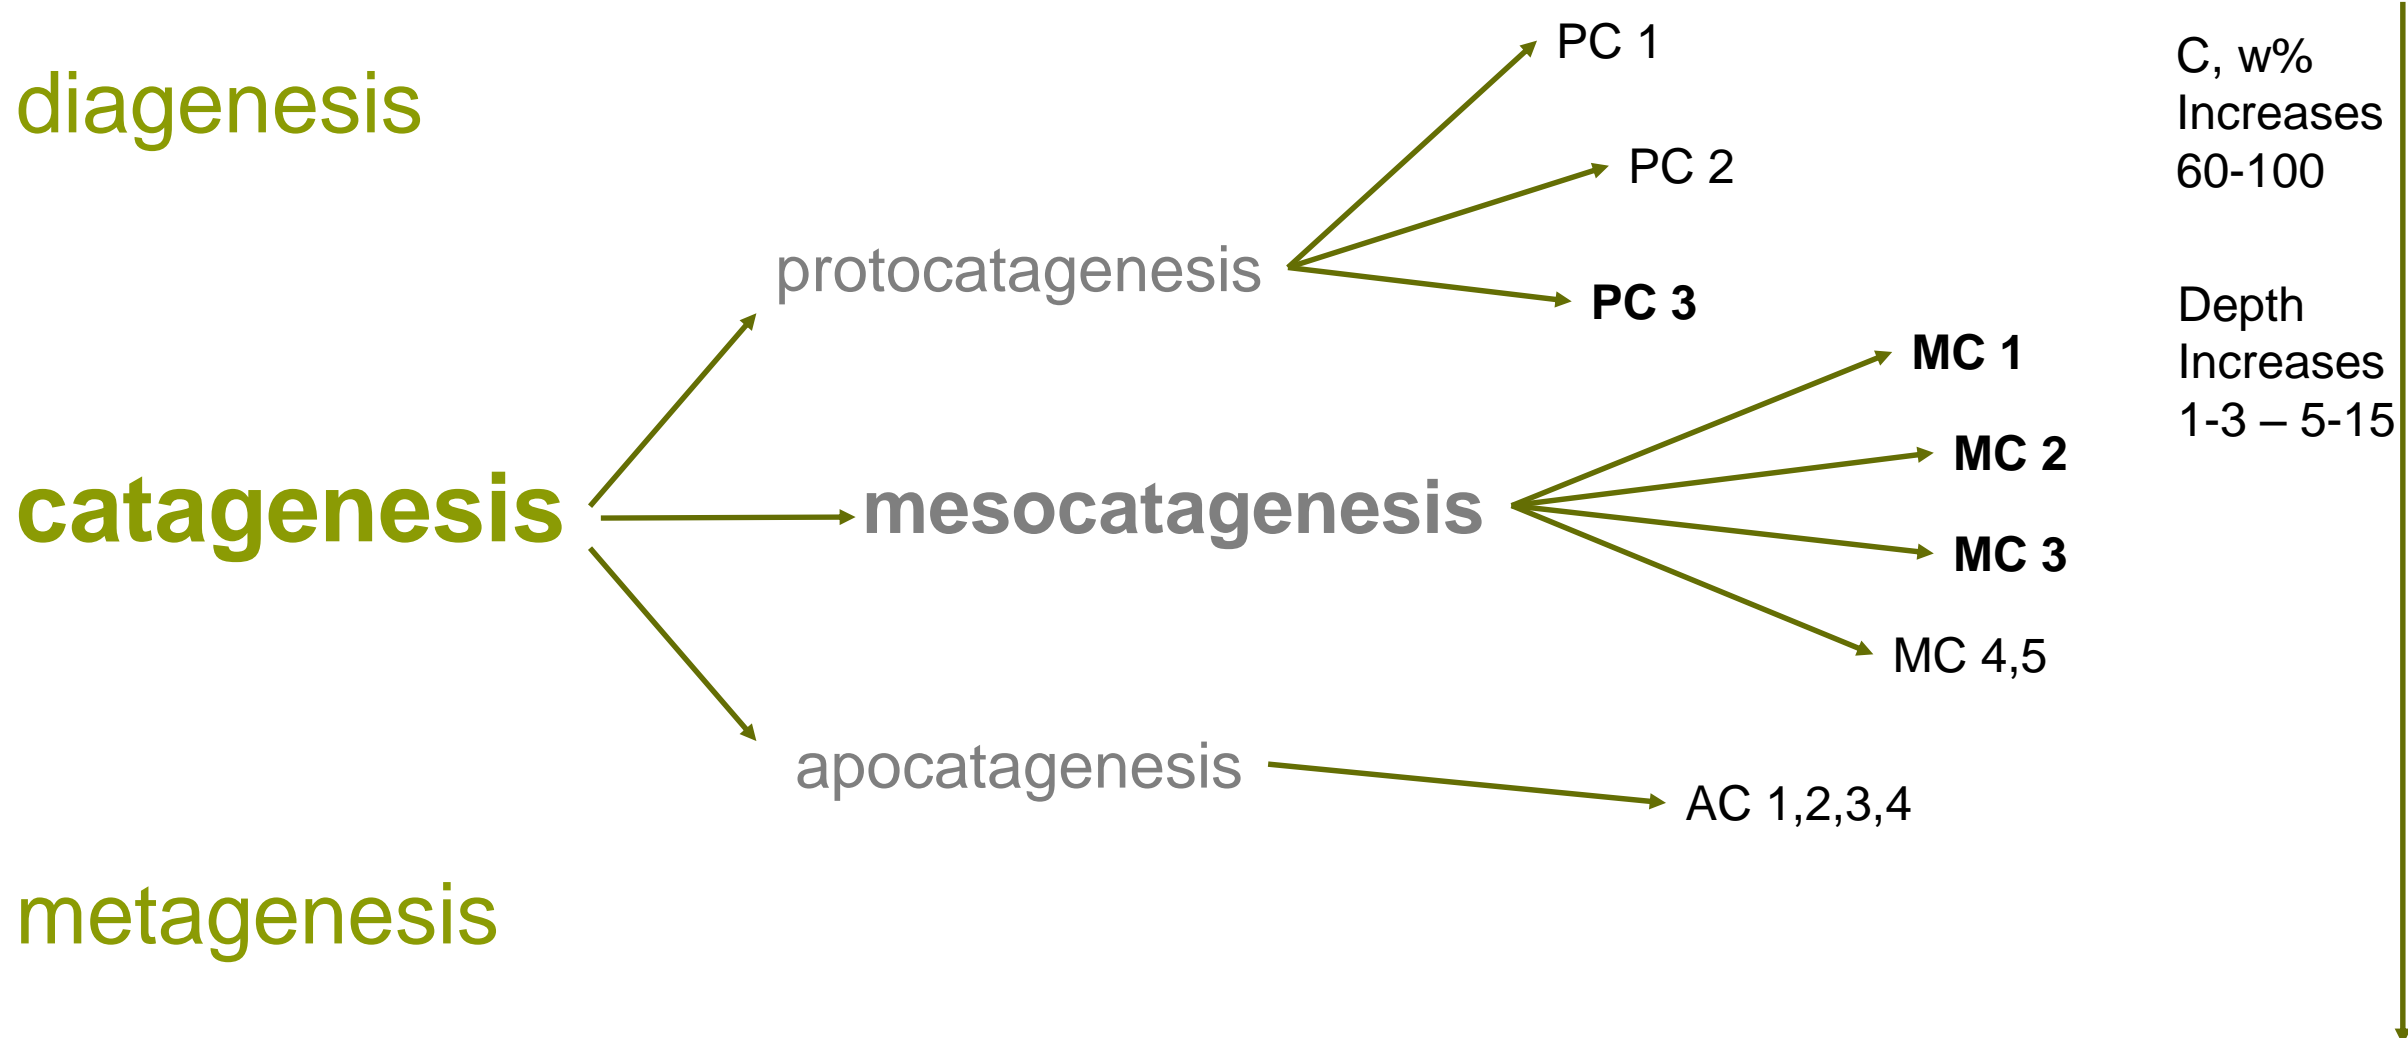

- What is kerogen? Is there any difference between samples from different wells?
- What structure kerogen has? What's the mechanism of its decomposition?
- How to learn is it worth it to make production from certain kerogen?
- How efficiently obtain hydrocarbons from it? Which types of HC will we get?

Kerogen

M. Vandenbroucke, C. Largeau / Organic Geochemistry 38 (2007) 719–833

Kerogen genesis

The main oil window exists at within range from PC3 till MC3

Methods

- **Analysis of kerogen structure**

 - Nuclear magnetic resonance (NMR)

 - X-ray photoelectron spectroscopy (XPS)

 - CHNS analysis

- **Kerogen properties investigation and analysis of thermal destruction products**

 - Pyrolysis

 - Kinetic experiments

 - Coupled two-dimensional gas chromatography with mass spectrometry

Solid State Nuclear Magnetic Resonance

3 Main Problems

$$H_{\text{loc}} \propto \mu_{\text{h}} (1 - 3\cos^2\phi)/r^3$$

NMR techniques

➤ ^1H MAS NMR

Main drawback of this method – too broad signals, which makes impossible detailed structure investigation. Can be used to analyze relative contribution of aromatic and aliphatic fragments.

➤ ^{13}C CP MAS NMR

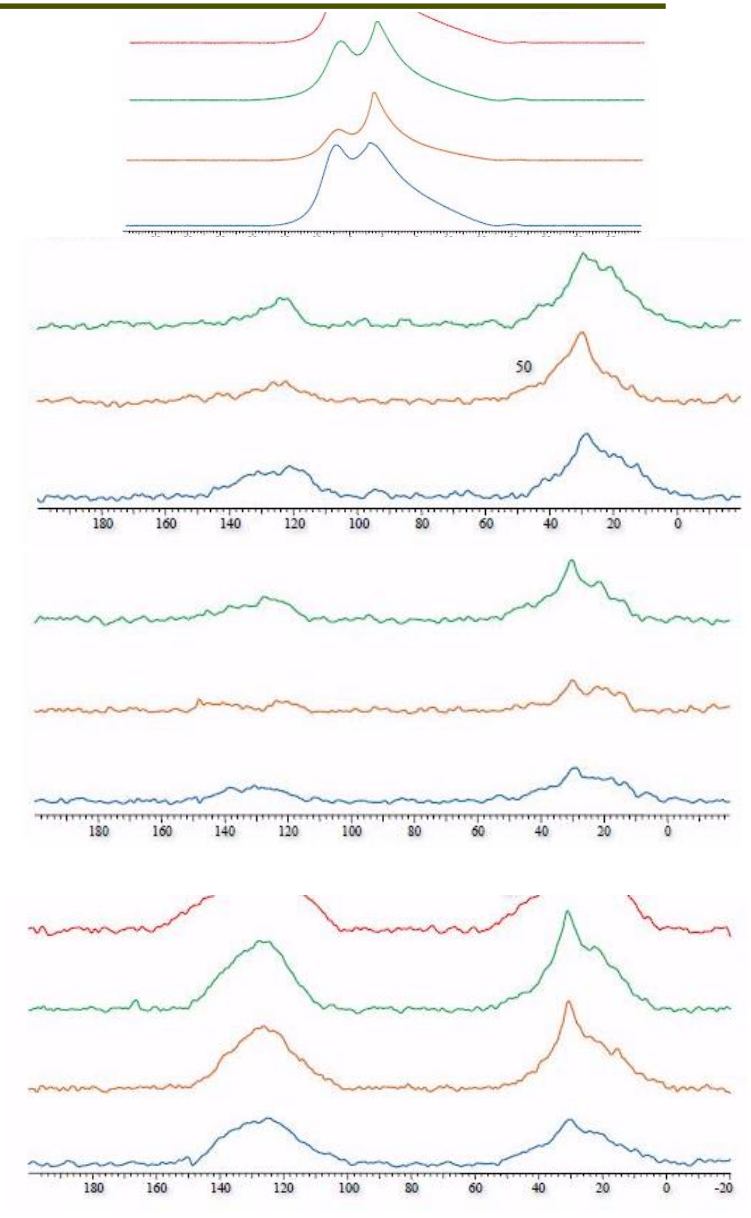

Cross-polarization NMR relies on the presence of an abundant spin system (^1H) to enhance the observation of a signal from a dilute spin system (^{13}C). The idea is to transfer polarization (hence signal intensity) from the abundant ^1H spins to the dilute ^{13}C spins.

➤ ^{13}C CP DD MAS NMR

This modification (dipolar dephasing) of cross-polarization technique is used for selective observation of tertiary ^{13}C atoms, due to their low dipole-dipole interactions, and mobile aliphatic chains with low effective cp.

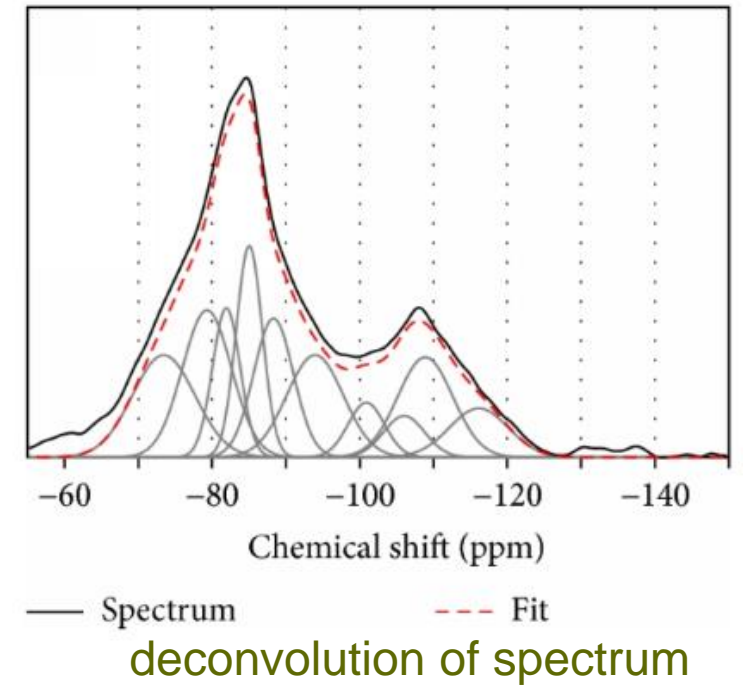

➤ ^{13}C DP MAS NMR

Experiments with direct polarization of ^{13}C atoms. Can be used for quantitative analysis. However, due to low natural abundance of ^{13}C and long-spin relaxation times, time of experiment increases significantly

0%	12.6%	32.2%	0%	23.8%	28.4%

Kinetics Theory: Reaction rate

A,B,C,D – substances; a,b,c,d – stoichiometric coefficients

$$r = -\frac{1}{a} \frac{d[A]}{dt} = -\frac{1}{b} \frac{d[B]}{dt} = \frac{1}{c} \frac{d[C]}{dt} = \frac{1}{d} \frac{d[D]}{dt}$$

Reaction rate **r** – change of substance amount in time

$$r = k [A]^x [B]^y$$

Reaction constant **k** – every aspect of reaction except [C]

x, y – orders of reaction, with respect to substances (A, B), not related with a, b

$$n = x + y$$

n - reaction order

Arrhenius equation

$$k = Ae^{-\frac{E_a}{RT}}$$

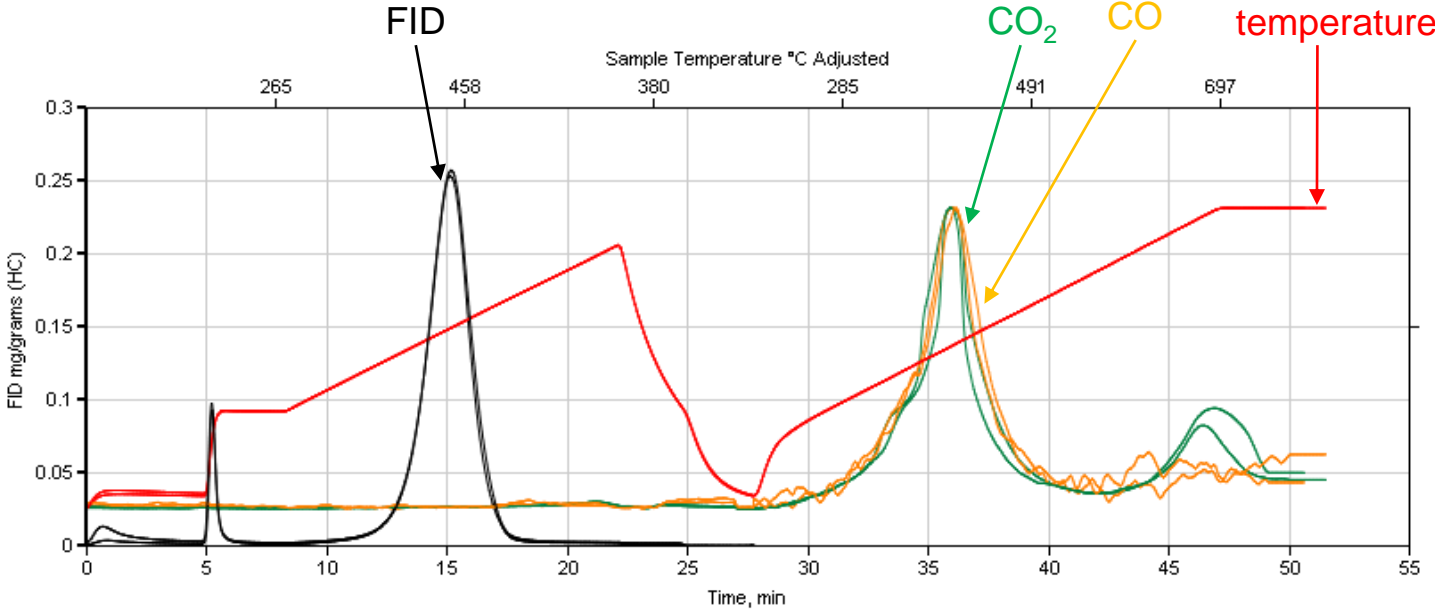

A – frequency factor (probability of a favorable collision between two atoms)

$$\frac{d[\text{Kerogen}]}{dt} = -kt = -Ae^{-\frac{E_a}{RT}}$$

HAWK pyrolysis instrument

Energy activation distribution

$$\alpha = -\frac{dC}{dt} = \sum_i \frac{dC_i}{dt} = \sum_i -Ae^{\frac{-E_{a_i}}{RT}} t$$
